Agent Memory

Fresh agents. Persistent goals. Better next attempts.

Every new question starts with a fresh context. The agent receives the active goal, relevant knowledge, and the next unfinished step.

What persists

Goal state: the objective, constraints, progress, and next action.
Knowledge: verified facts and their sources.
Procedures: methods, when they apply, and how to check them.
Evidence: attempts, results, and the code that was tested.

How it gets better

Try → verify → save the lesson → improve the next choice.

Requirements rule out invalid outcomes. Failed attempts discourage repeating the same mistake. Successful procedures become preferred starting points when their conditions match. Changed conditions trigger a recheck.

Example: an export exceeds its memory limit because a helper buffers the whole file. The next agent starts by fixing that helper, using the saved diagnosis and tests.

How goals stay separate

Each goal has its own **Git repository and workspace**. Switching subjects selects another goal. Only selected, applicable lessons cross between them.

What makes this work

A runner starts fresh contexts, supplies the brief, saves progress, and requires the goal's checks before recording success. The model stays the same; its starting information and choices improve through evidence.

Proposed design. Lessons guide the search; they do not guarantee success.
